Linked Pointers

Data Structures C++ for C Coders

한동대학교 김영섭 교수 idebtor@gmail.com

Singly Linked List Concepts

```
int z = 25;  // define an int
int* p;  // declare an integer pointer
p = &z;  // p holds the address of z
// p points z
```

??

Z

```
int z = 25;  // define an int

int* p;  // declare an integer pointer

p = &z;  // p holds the address of z

// p points z
```

25

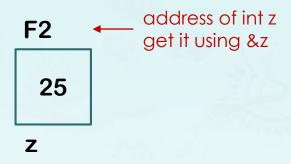

Z

```
int z = 25;  // define an int

int* p;  // declare an integer pointer

p = &z;  // p holds the address of z

// p points z
```

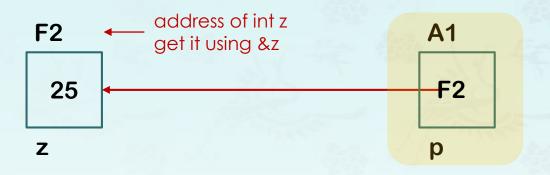

```
int z = 25;  // define an int

int* p;  // declare an integer pointer
p = &z;  // p holds the address of z
// p points z
```

```
int z = 25;  // define an int
int* p;  // declare an integer pointer
p = &z;  // p holds the address of z
// p points z
```

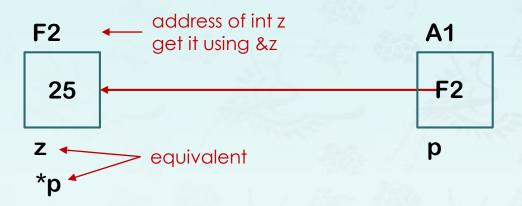

What is *p?

```
int z = 25;  // define an int

int* p;  // declare an integer pointer

p = &z;  // p holds the address of z

// p points z
```

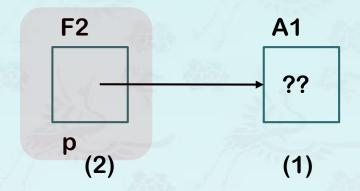

If p is a pointer, *p is the thing it is pointing at. Therefore, *p = 25;

```
int* p = new int;
```

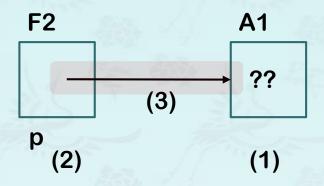

- 1) 'new int;' declares an integer storage space in memory
- 2) 'int *p' makes create a pointer to point an integer storage
- 3) `=` makes the pointer point at an integer storage.

```
int* p = new int;
```

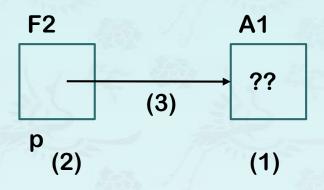

- 1) 'new int;' declares an integer storage space in memory
- 2) 'int *p' makes create a pointer to point an integer storage
- 3) `=` makes the pointer point at an integer storage.

```
int* p = new int;
```

- 1) 'new int;' declares an integer storage space in memory
- 2) 'int *p' makes create a pointer to point an integer storage
- 3) `=` makes the pointer point at an integer storage.

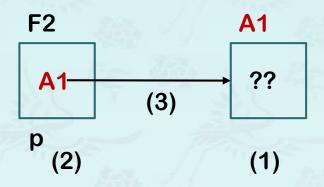

```
int* p = new int;
```

- 1) 'new int;' declares an integer storage space in memory
- 2) 'int *p' makes create a pointer to point an integer storage
- 3) `=` makes the pointer point at an integer storage.

What is really happening in (3)?

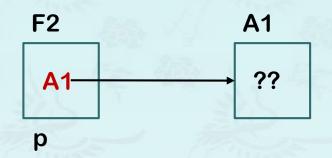

```
int* p = new int;
```

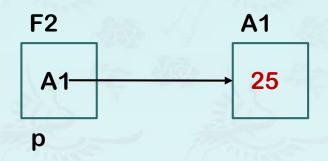

- 1) 'new int;' declares an integer storage space in memory
- 2) 'int *p' makes create a pointer to point an integer storage
- 3) `=` makes the pointer point at an integer storage.

What is really happening in (3)?

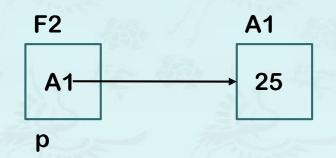

```
int* p = new int;
*p = 25;
```

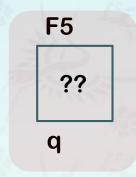

```
int* p = new int;
*p = 25;
```

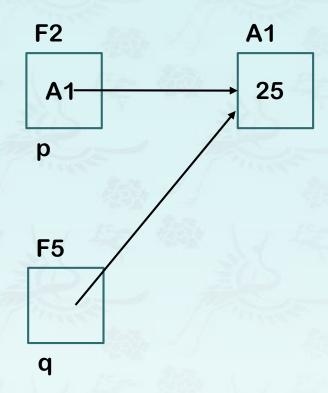

```
int* p = new int;
*p = 25;
cout << *p << endl;
int* q;</pre>
```

- 1) 'int* q;' declares a pointer,
- 2) but it doesn't point anywhere (it's uninitialized) and
- 3) the statement doesn't assign any memory for the integer data.

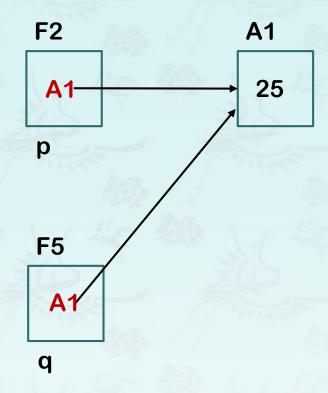

```
int* p = new int;
*p = 25;
cout << *p << endl;
int* q;
q = p;</pre>
```

What is really happening in (q = p)?

- 1) `q = p`; means that `q` is pointing to the same place `p` is pointing at.
- 2) it does not mean that `q` is pointing at `p`.

```
int* p = new int;
*p = 25;
cout << *p << endl;
int* q;
q = p;</pre>
```

What is really happening in (q = p)?

- 1) `q = p`; means that `q` is pointing to the same place `p` is pointing at.
- 2) it does not mean that `q` is pointing at `p`.

Pointer reviewed

```
int* p = new int;
*p = 25;
cout << *p << endl;
int* q;
q = p;
cout << *q;</pre>
```

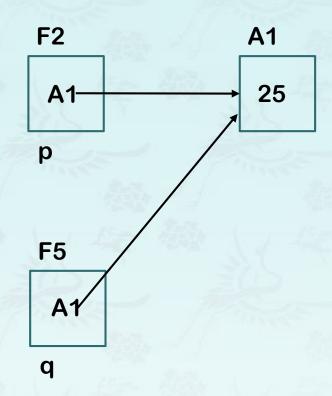

```
int* p = new int(25);

cout << *p << endl;
int* q = p;

cout << *q;</pre>
```

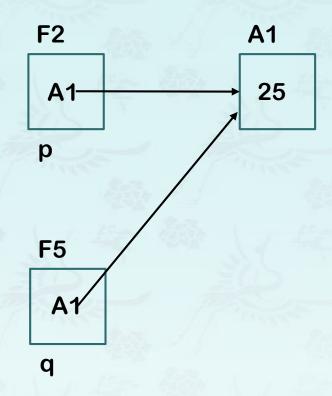

```
int* p = new int(25);
cout << *p << endl;
int* q = p;
cout << *q;
*q = 34;
q = new int(56); // don't change
p = new int(78); // don't change
delete p;
delete q;</pre>
```

- 1. Complete the memory diagram based on the code above.
- 2. Debug code.

```
int* p = new int(25);
cout << *p << end1;
int* q = p;
cout << *q;

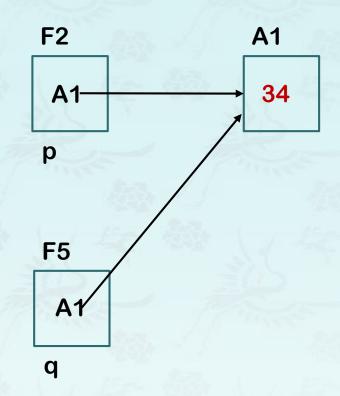

*q = 34;
q = new int(56);
p = new int(78);
delete p;
delete q;</pre>
```

1) What is the effect of assigning a new value to `*q=34`?

```
int* p = new int(25);
cout << *p << endl;
int* q = p;
cout << *q;

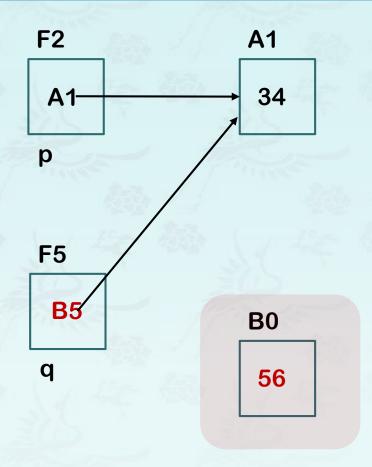

*q = 34;
q = new int(56);
p = new int(78);
delete p;
delete q;</pre>
```

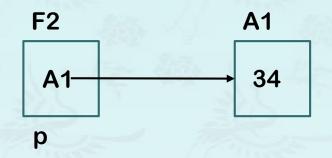

1) What is the effect of assigning a new value to `*q=34`?

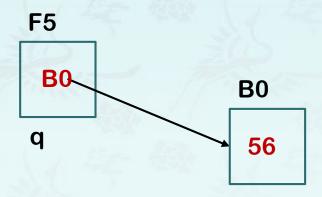

Any changes to `*q` will also affect `*p`.

```
int* p = new int(25);
cout << *p << endl;
int* q = p;
cout << *q;
*q = 34;
q = new int(56);
p = new int(78);
delete p;
delete q;</pre>
```

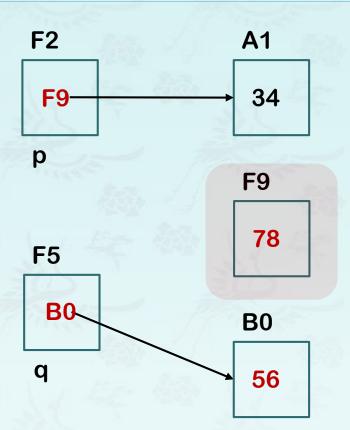

```
int* p = new int(25);
cout << *p << endl;
int* q = p;
cout << *q;
*q = 34;
q = new int(56);
p = new int(78);
delete p;
delete q;</pre>
```

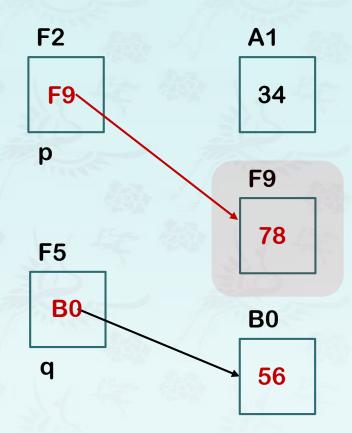

```
int* p = new int(25);
cout << *p << end1;
int* q = p;
cout << *q;
*q = 34;
q = new int(56);
p = new int(78);
delete p;
delete q;</pre>
```

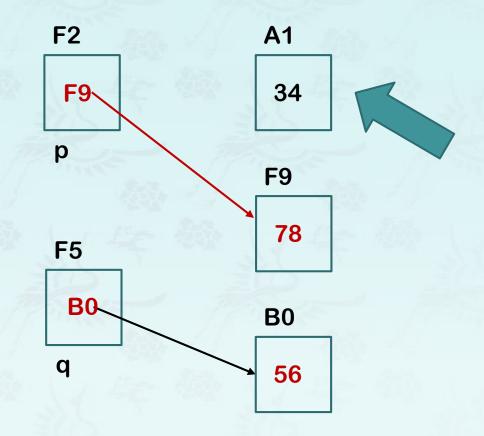

```
int* p = new int(25);
cout << *p << endl;
int* q = p;
cout << *q;
*q = 34;
q = new int(56);
p = new int(78);
delete p;
delete q;</pre>
```

1) What do you observe in result?

```
int* p = new int(25);
cout << *p << endl;
int* q = p;
cout << *q;
*q = 34;
q = new int(56);
p = new int(78);
delete p;
delete q;</pre>
```

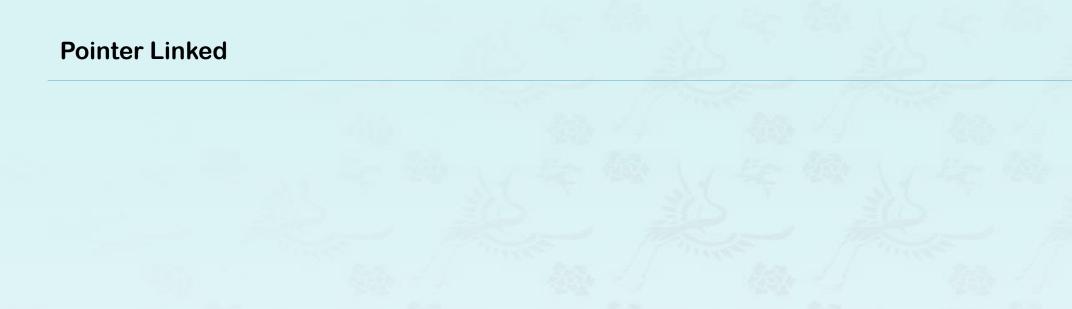

1) What do you observe in result? Unfortunately by moving `p` from `34` to `78` we have no way of getting back hold of `34`.

```
F2
                                                                    A1
int* p = new int(25);
cout << *p << endl;</pre>
                                Example 2
                                                                     34
int* q = p;
                                                                                   garbage
cout << *q;
                                                   p
*q = 34;
                                                                     F9
q = new int(56);
p = new int(78);
                                                                      78
                                                   F5
delete p;
delete q;
                                                                     B<sub>0</sub>
                                                   q
                                                                     56
```

It is now floating in memory, taking up space which we can't re-use. This effect is known as **memory** leakage, and the piece of memory containing the `34` is known as **garbage**. The runtime systems of some languages have garbage collection built in, but C++ doesn't and you have to be careful. If you leak too much memory, the system will run out of RAM and crash!

```
F2
                                                                         A1
int* p = new int(25);
cout << *p << endl;</pre>
                                  Example 2
                                                        F9
                                                                          34
int* q = p;
                                                                                         garbage
cout << *q;
                                                       p
*q = 34;
                                                                          F9
q = new int(56);
p = new int(78);
delete p;
                                                                           78
                                                       F5
delete p;
delete q;
                                                        BO
                                                                          B<sub>0</sub>
                                                       q
                                                                           56
```

Before you let go of the object you are pointing at, you have to `delete` it.

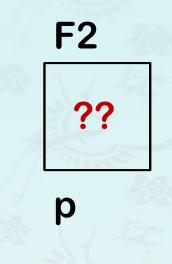

```
class Node {
public:
   int data;
   Node* next;
};

int main() {
   Node* p = new Node;
   ...
}
```

```
class Node {
public:
   int data;
   Node* next;
};

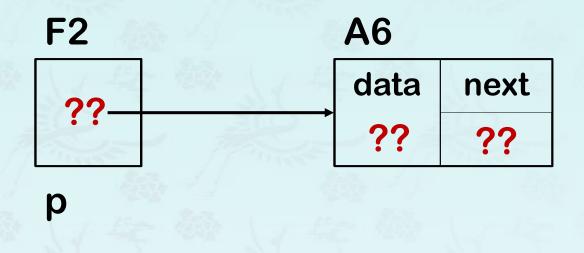

int main() {
   Node* p = new Node;
   ...
}
```

- (1) This code declares a **Node pointer**, **p**, and
- (2) allocate memory space for a **new Node** and
- (3) make **p point at** it.

```
class Node {
public:
   int data;
   Node* next;
};

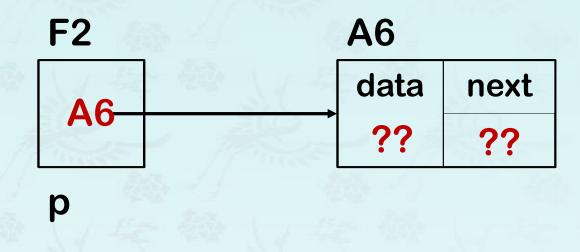

int main() {
   Node* p = new Node;
   ...
}
```

- (1) This code declares a **Node pointer**, **p**, and
- (2) allocate memory space for a **new Node** and
- (3) make **p point at** it.

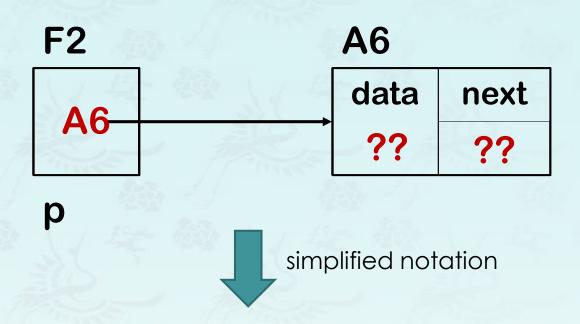

```
class Node {
public:
   int data;
   Node* next;
};

int main() {
   Node* p = new Node;
   ...
}
```

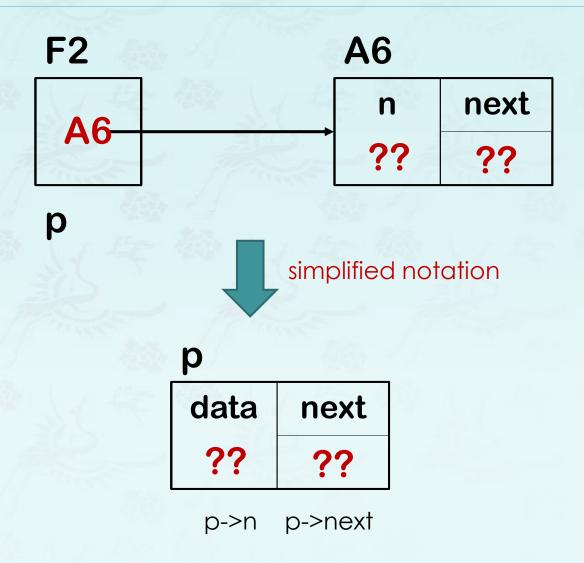

- (1) This code declares a **Node pointer**, **p**, and
- (2) allocate memory space for a **new Node** and
- (3) make **p point at** it.

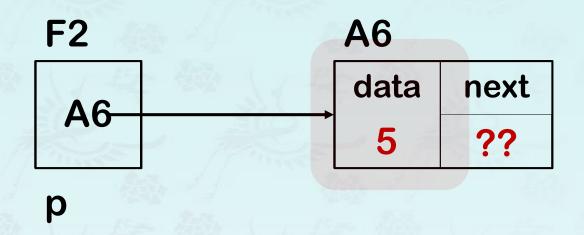

```
class Node {
public:
  int data;
 Node* next;
};
int main( ) {
 Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p->next = q;
```

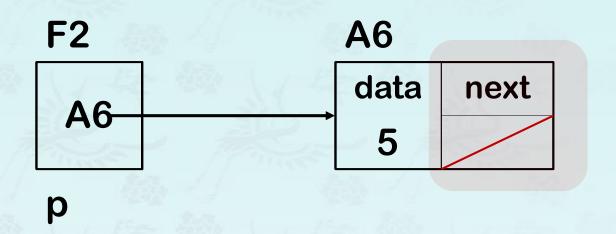

```
class Node {
public:
  int data;
 Node* next;
};
int main( ) {
  Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p->next = q;
```

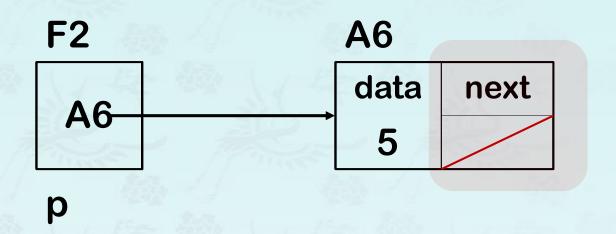

```
class Node {
public:
  int data;
 Node* next;
int main( ) {
 Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
 Node* q = new Node;
 q \rightarrow data = 3;
 q->next = nullptr;
  p->next = q;
```

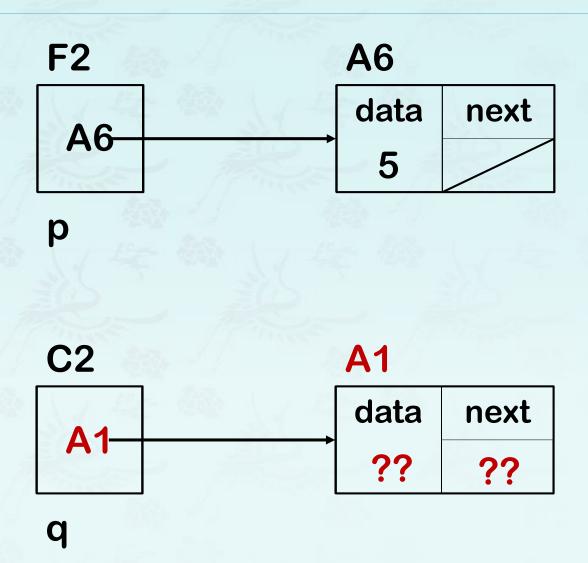

```
class Node {
public:
  int data;
 Node* next;
int main( ) {
 Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
 Node* q = new Node;
 q \rightarrow data = 3;
 q->next = nullptr;
  p->next = q;
```

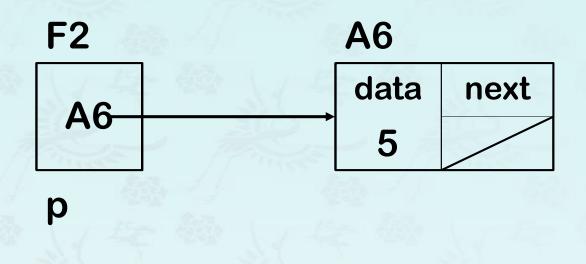

```
class Node {
public:
  int data;
 Node* next;
int main( ) {
 Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
 Node* q = new Node;
 q \rightarrow data = 3;
 q->next = nullptr;
  p->next = q;
```

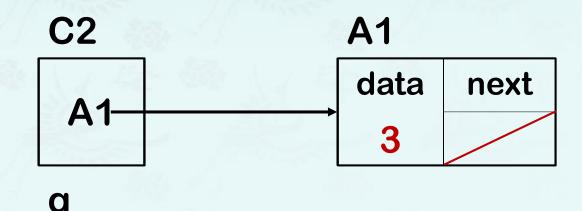

```
class Node {
public:
  int data;
 Node* next;
};
int main( ) {
  Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p->next = q;
```

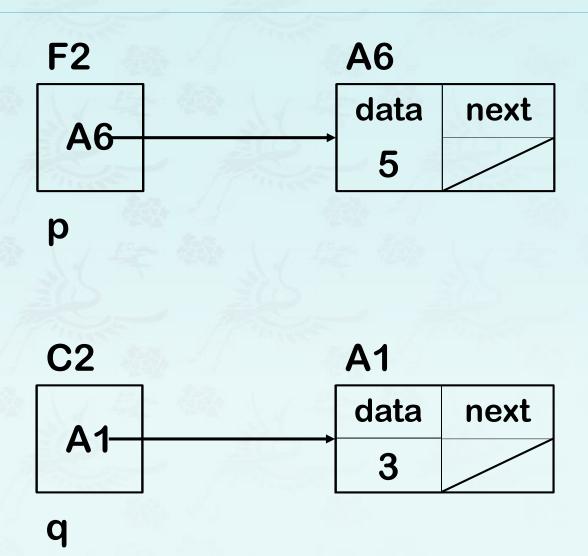

```
class Node {
public:
  int data;
 Node* next;
};
int main( ) {
  Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p->next = q;
```

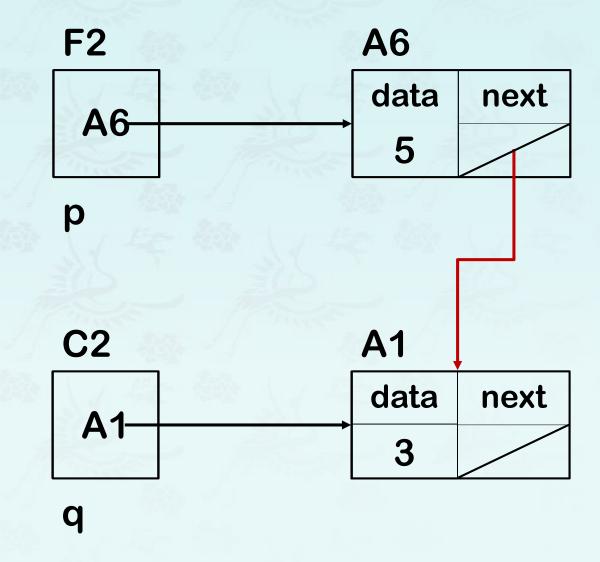

```
class Node {
public:
  int data;
 Node* next;
};
int main( ) {
  Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p \rightarrow next = q;
```

```
class Node {
public:
  int
         data;
  Node* next;
int main( ) {
  Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p \rightarrow next = q;
```

What should be corrected in the figure?

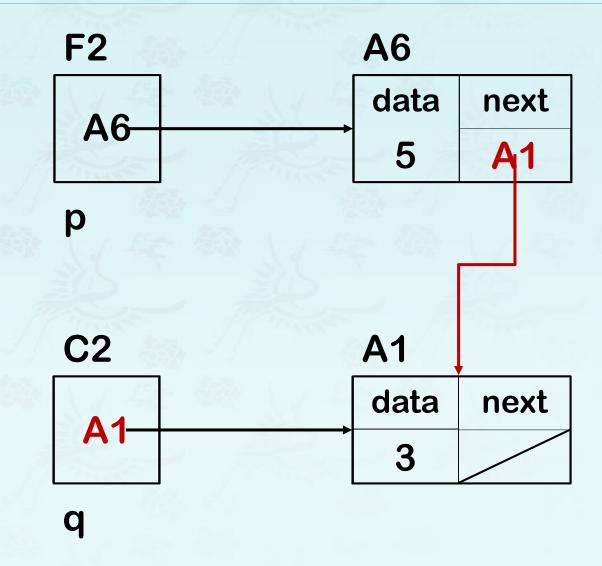

```
class Node {
public:
  int data;
  Node* next;
};
int main( ) {
  Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p \rightarrow next = q;
```

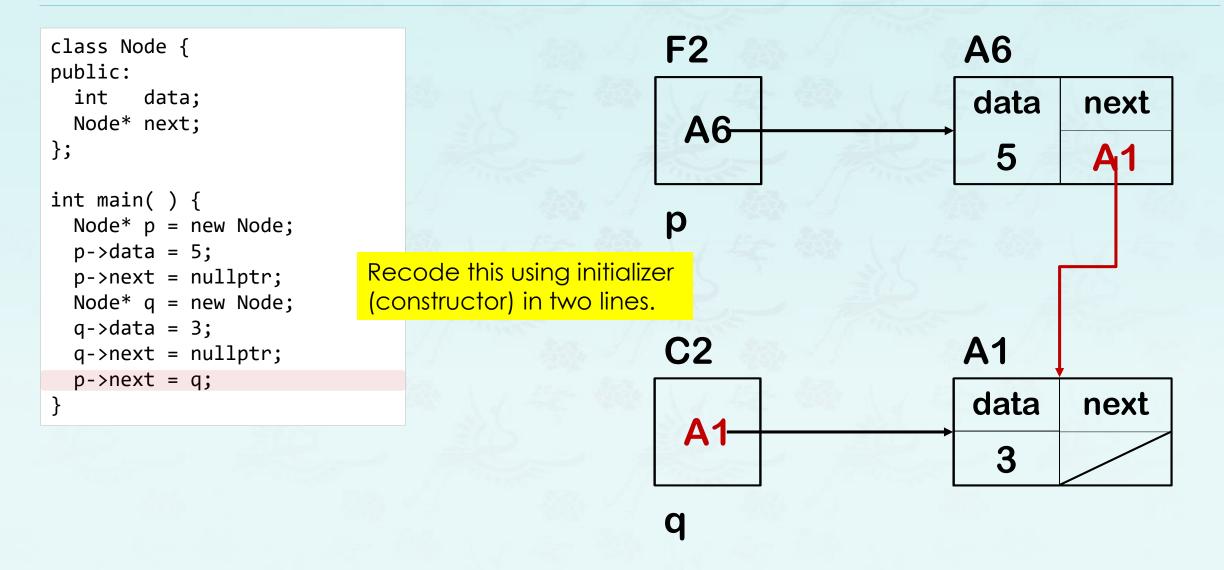

What should be corrected in the figure?

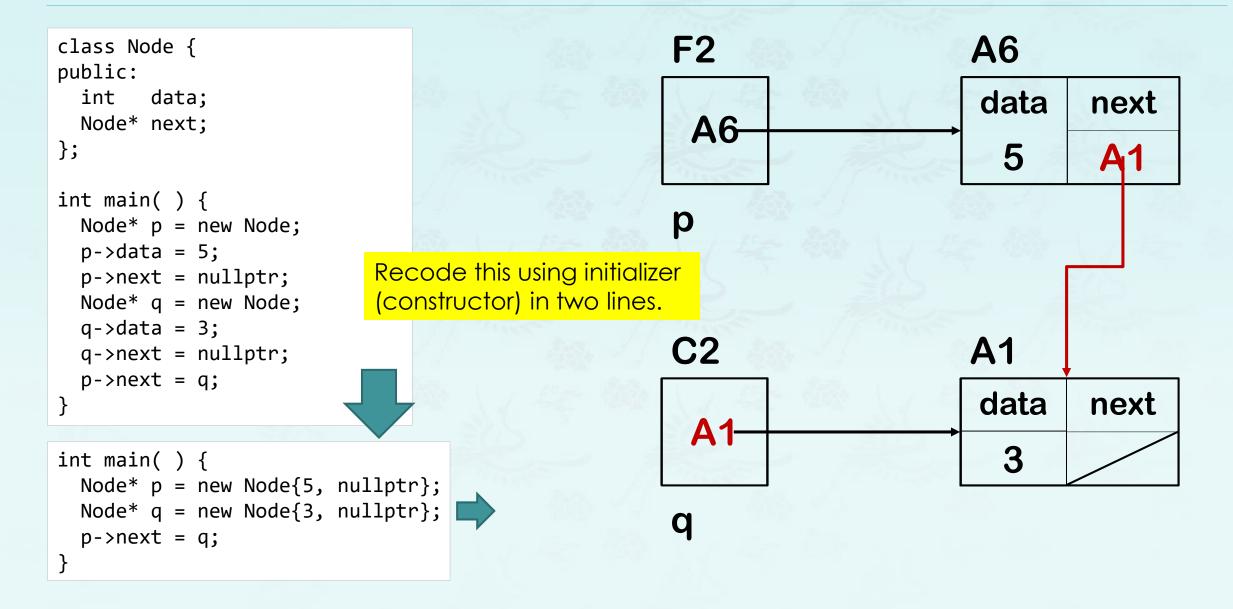

p->next = A1;

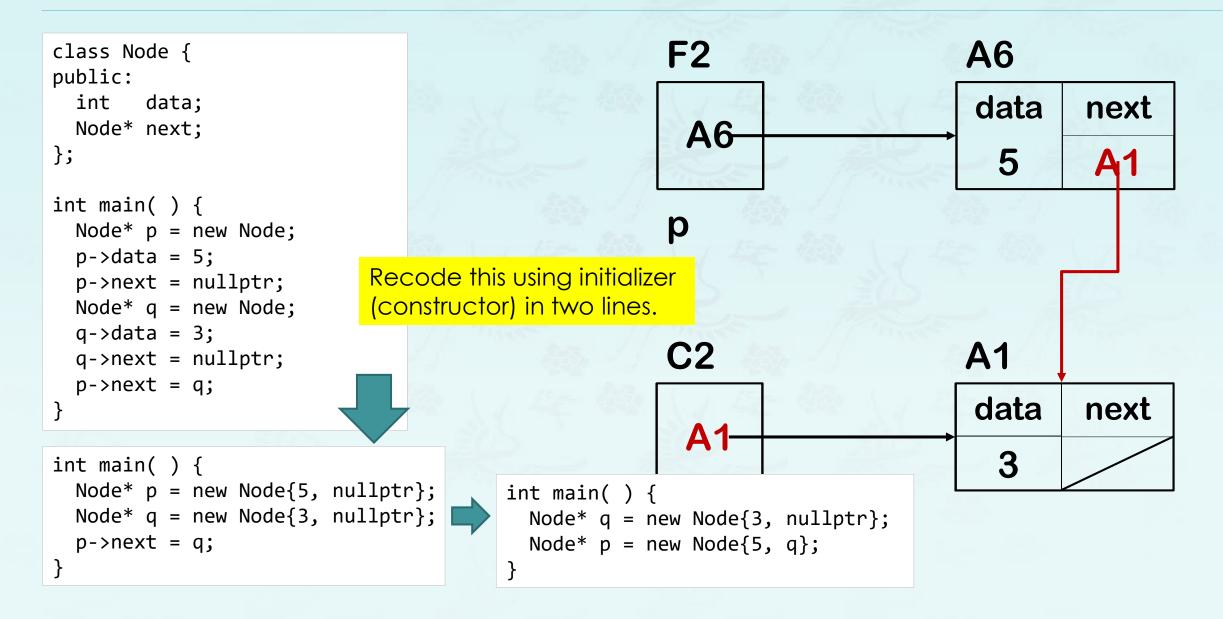

```
class Node {
public:
  int data;
  Node* next;
};
int main( ) {
  Node* p = new Node;
  p->data = 5;
  p->next = nullptr;
  Node* q = new Node;
  q \rightarrow data = 3;
  q->next = nullptr;
  p \rightarrow next = q;
```

What should be corrected in the figure?

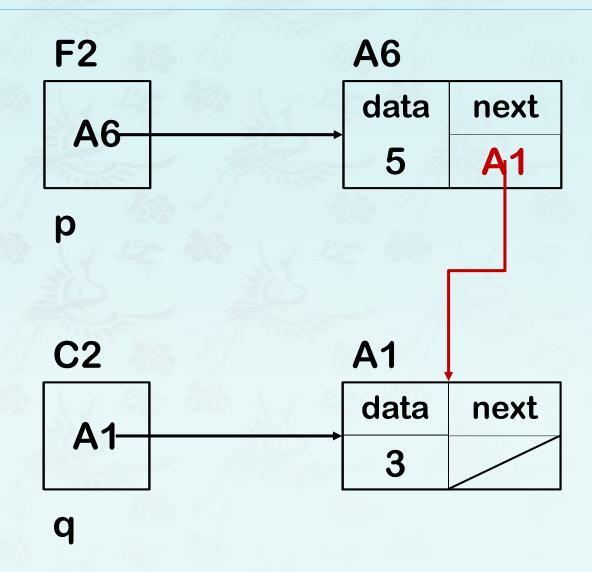

By stringing many of these Node objects together we can create a structure called a **singly-linked list**;

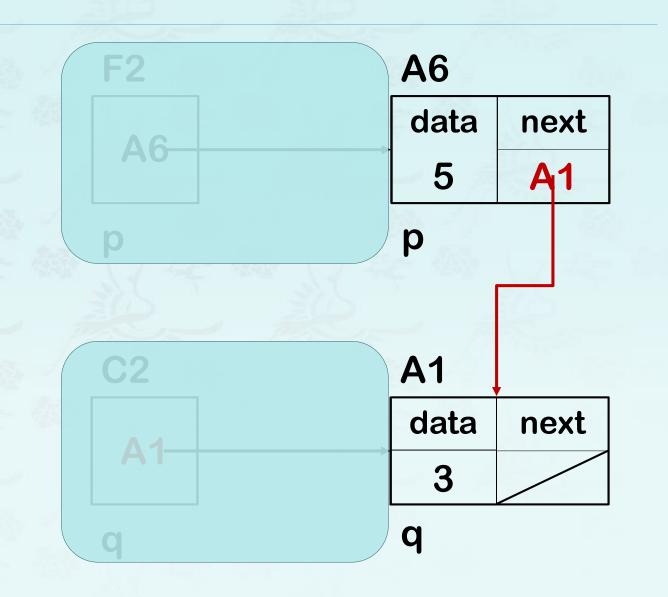

Hide p and q, and you may see a singly linked list clearly.

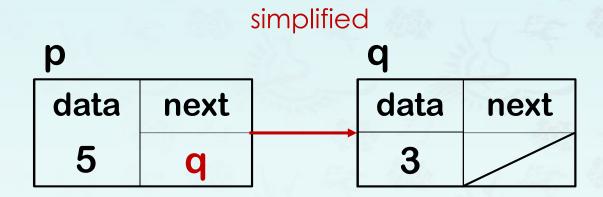

```
class Node {
public:
   int data;
   Node* next;
};

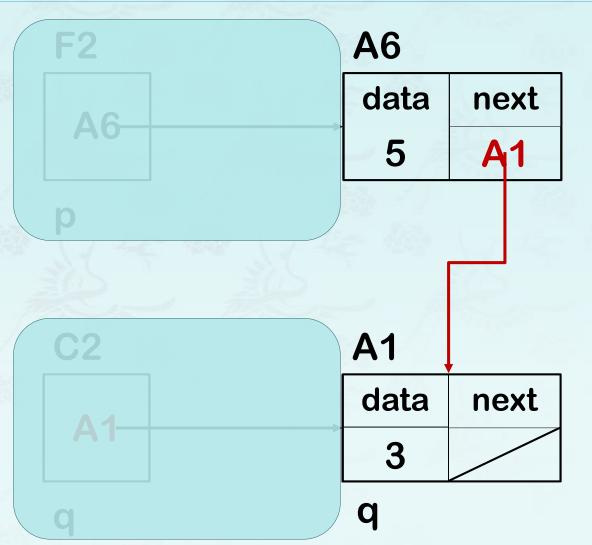

int main() {
   Node* q = new Node{3, nullptr};
   Node* p = new Node{5, q};
}
```

Hide p and q, and you may see a singly linked list clearly.

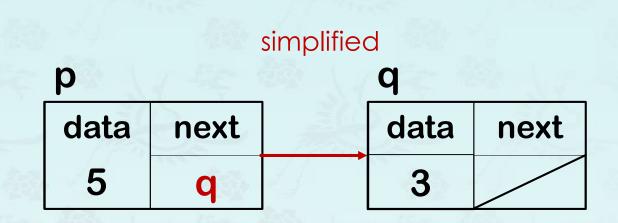

By stringing many of these Node objects together we can create a structure called a **singly-linked list**;

```
class Node {
public:
   int data;
   Node* next;
};

int main() {
   Node* q = new Node{3, nullptr};
   Node* p = new Node{5, q};
}
```

Pointer Linked – Quiz and Lab

```
#include <iostream>
using namespace std;
class Node {
public:
  char ch;
  Node* next;
};
int main( ) {
  Node* p = nullptr, *q = nullptr;
  char ch;
  while (cin.get(ch) && ch != '\n') {
    p = new Node;
    p \rightarrow ch = ch;
    p \rightarrow next = q;
    q = p;
  while (p != nullptr) {
    cout.put(p->ch);
    p = p->next;
  cout << endl;</pre>
```

Assuming the input A, B, C, D to this program, what would be the data structure after the input?

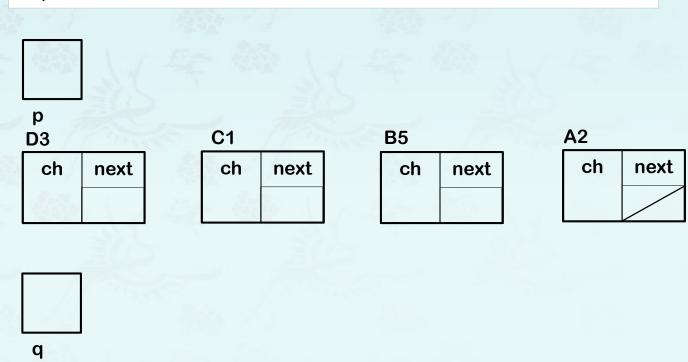

Draw a figure to represent the data structure in memory. Use a mnemonic memory address to represent each node such as A2, B5, C1, ..., etc.

Pointer Linked – Lab

```
#include <iostream>
using namespace std;
class Node {
public:
  char ch;
  Node* next;
};
int main( ) {
  Node* p = nullptr, *q = nullptr;
  char ch;
  while (cin.get(ch) && ch != '\n') {
    p = new Node;
    p \rightarrow ch = ch;
    p \rightarrow next = q;
    q = p;
  while (p != nullptr) {
    cout.put(p->ch);
    p = p \rightarrow next;
  cout << endl;</pre>
```

Assuming the input A, B, C, D to this program, what would be the data structure after the input?

Draw a figure to represent the data structure in memory. Use a mnemonic memory address to represent each node such as A2, B5, C1, ..., etc.

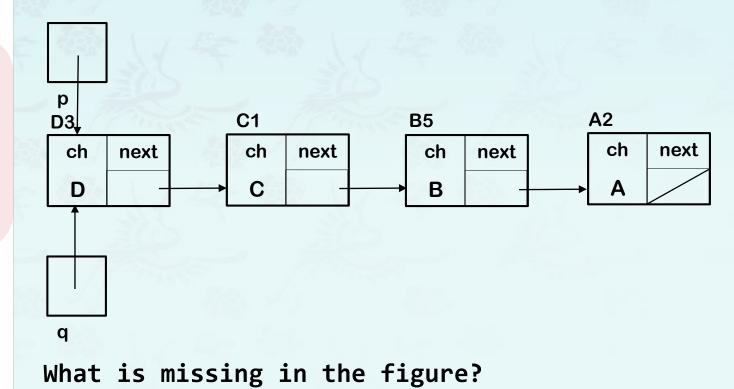

What is missing in the figure?

Pointer Linked – Lab

```
#include <iostream>
using namespace std;
class Node {
public:
  char ch;
  Node* next;
};
int main( ) {
  Node* p = nullptr, *q = nullptr;
  char ch;
  while (cin.get(ch) && ch != '\n') {
    p = new Node;
    p \rightarrow ch = ch;
    p \rightarrow next = q;
    q = p;
  while (p != nullptr) {
    cout.put(p->ch);
    p = p \rightarrow next;
  cout << endl;</pre>
```

Assuming the input A, B, C, D to this program, what would be the data structure after the input?

Draw a figure to represent the data structure in memory. Use a mnemonic memory address to represent each node such as A2, B5, C1, ..., etc.

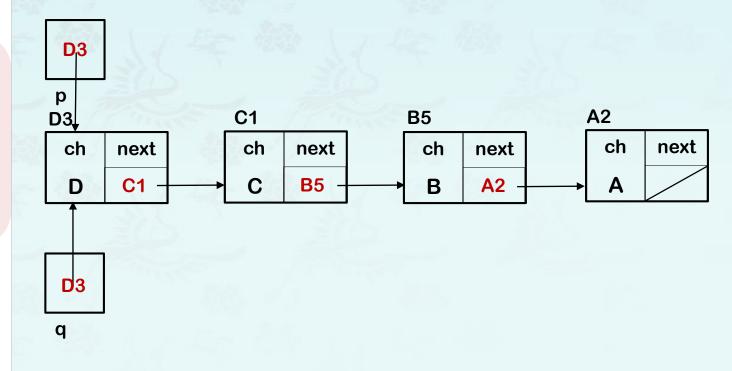

Pointer Linked – Lab

```
#include <iostream>
using namespace std;
class Node {
public:
  char ch;
  Node* next;
};
int main( ) {
  Node* p = nullptr, *q = nullptr;
  char ch;
  while (cin.get(ch) && ch != '\n') {
    p = new Node;
    p \rightarrow ch = ch;
    p \rightarrow next = q;
    q = p;
  while (p != nullptr) {
    cout.put(p->ch);
    p = p \rightarrow next;
  cout << endl;</pre>
```

Assuming the input A, B, C, D to this program, what would be the data structure after the input?

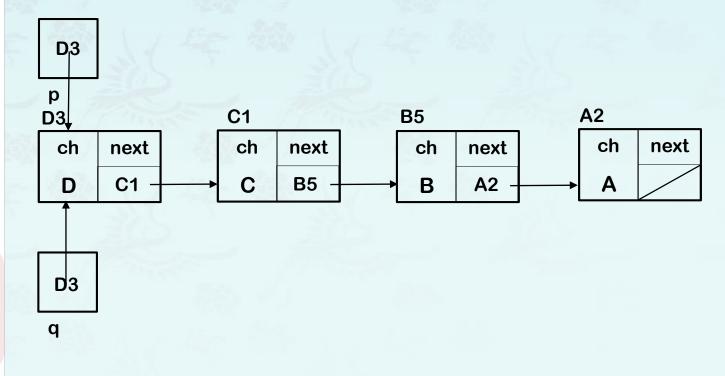

Draw a figure to represent the data structure in memory. Use a mnemonic memory address to represent each node such as A2, B5, C1, ..., etc.

Pointer Linked – Quiz

```
#include <iostream>
using namespace std;
class Node {
public:
  char ch;
  Node* next;
};
int main( ) {
  Node* p = nullptr, *q = nullptr;
  char ch;
  while (cin.get(ch) && ch != '\n') {
    p = new Node;
    p \rightarrow ch = ch;
    p \rightarrow next = q;
    q = p;
  while (p != nullptr) {
    cout.put(p->ch);
    p = p->next;
  cout << endl;</pre>
```

After executing the while loop, What is the output? What is the values of p and q?

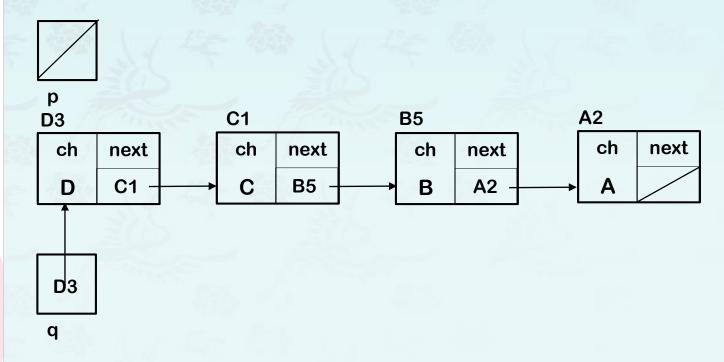

Pointer Linked – Quiz

```
#include <iostream>
using namespace std;
class Node {
public:
  char ch;
  Node* next;
};
int main( ) {
  Node* p = nullptr, *q = nullptr;
  char ch;
  while (cin.get(ch) && ch != '\n') {
    p = new Node;
    p \rightarrow ch = ch;
    p \rightarrow next = q;
    q = p;
  while (p != nullptr) {
    cout.put(p->ch);
    p = p \rightarrow next;
  cout << endl;</pre>
```

If you run the code shown below at the end, what would be output?

cout << q->next->ch;

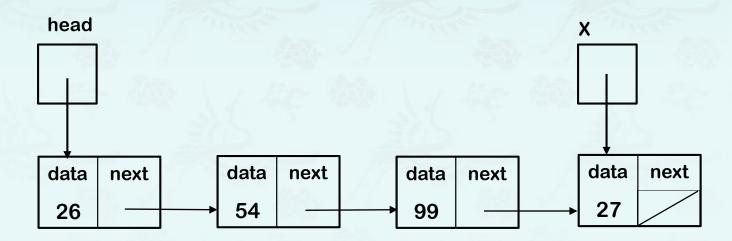

Dynamic Data Structures

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

basic member functions

- push_front()
- push_back()
- pop_front()
- pop_back()
- insert()
- remove()
- clear()

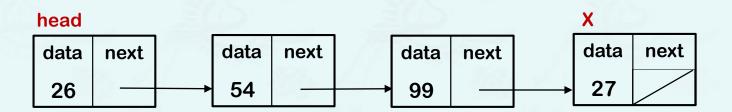

Dynamic Data Structures

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

basic member functions

- push_front()
- push_back()
- pop_front()
- pop_back()
- insert()
- remove()
- clear()

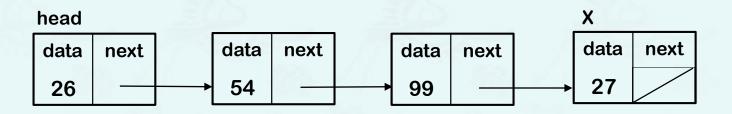

Dynamic Data Structures - push_front()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Let us imagine that we have created a linked list, where **head** points to the head of the list and **x** at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

Add a node (n = 10) at the head of list.

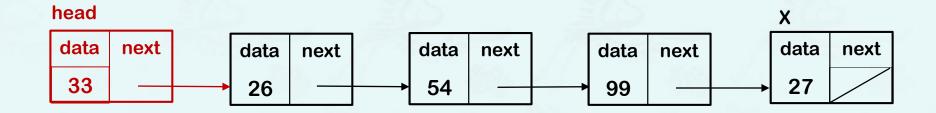

Dynamic Data Structures – push_front()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Add a node (n = 33) at the head of list.
 - create a node and initialized with n = 10.
 - let head point to the new node

```
y = new Node;
y->data = 33
y->next =
```

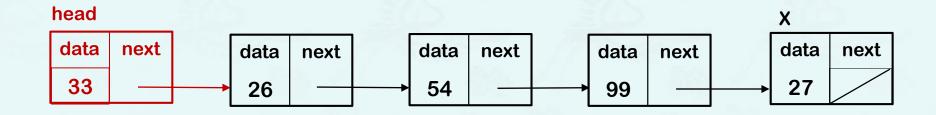

Dynamic Data Structures - push_front()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Add a node (n = 33) at the head of list.
 - create a node and initialized with n = 10.
 - let head point to the new node

```
y = new Node;
y->data = 33
y->next = head;
```

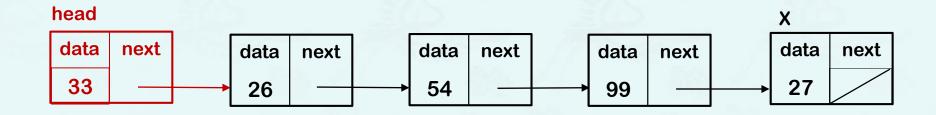

Dynamic Data Structures – push_front()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Add a node (n = 33) at the head of list.
 - create a node and initialized with n = 10.
 - let head point to the new node

```
y = new Node;
y->data = 33
y->next = head;
head =
```

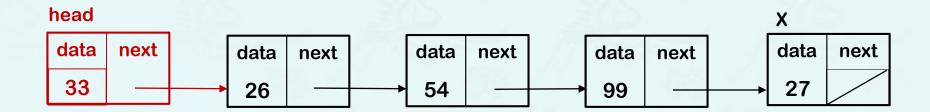

Dynamic Data Structures - push_front()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Add a node (n = 33) at the head of list.
 - create a node and initialized with n = 10.
 - let head point to the new node

```
y = new Node;
y->data = 33
y->next = head;
head = y;
```

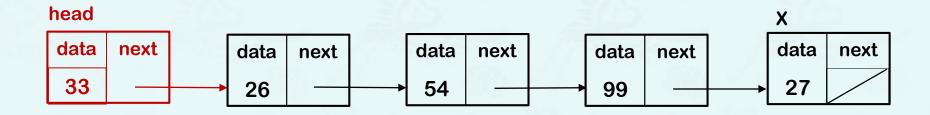

Dynamic Data Structures - push_front()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Add a node (n = 33) at the head of list.
 - create a node and initialized with n = 10.
 - let head point to the new node

```
y = new Node;
y->data = 33
y->next = head;
head = y;
y = new Node {33, head};
head = y;
```

Dynamic Data Structures – push_front()

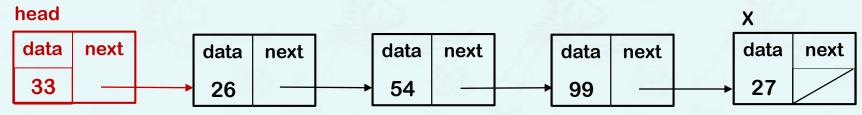

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Let us imagine that we have created a linked list, where **head** points to the head of the list and \mathbf{x} at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

- Add a node (n = 33) at the head of list.
 - create a node and initialized with n = 10.
 - let head point to the new node

```
y = new Node;
y->data = 33
y->next = head;
head = y;
y = new Node {33, head};
head = y;
```

How do you code it in a function, push_front()?

Dynamic Data Structures - push_front()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
...
head = push_front(head, 33);
```

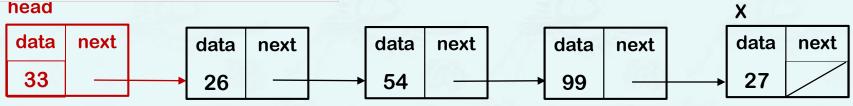

Let us imagine that we have created a linked list, where **head** points to the head of the list and \mathbf{x} at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

- Add a node (n = 33) at the head of list.
 - create a node and initialized with n = 10.
 - let head point to the new node

```
Node push_front(Node h, int d) {
    ...
    Node y = new Node{d, h};
    ...
    return y;
}
```

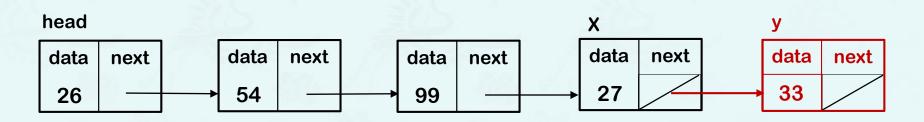

```
y = new Node;
y->data = 33
y->next = head;
head = y;
y = new Node {33, head};
head = y;
```

How do you code it in a function, push_front()?

Dynamic Data Structures - push_back()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

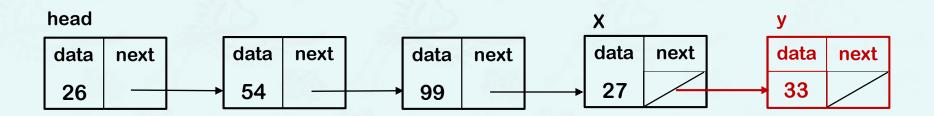

Dynamic Data Structures - push_back()

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Let us imagine that we have created a linked list, where **head** points to the head of the list and \mathbf{x} at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

• Add a node (n = 33) at the end of list.

```
y = new Node;
```

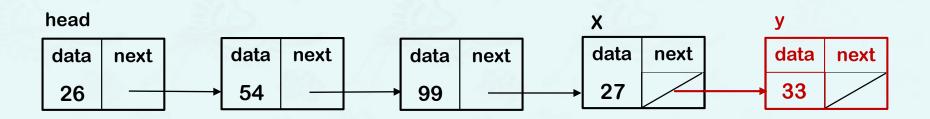

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Let us imagine that we have created a linked list, where **head** points to the head of the list and \mathbf{x} at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

Add a node (n = 33) at the end of list.

```
y = new Node;
y->data = 33
y->next = nullptr;
```

head

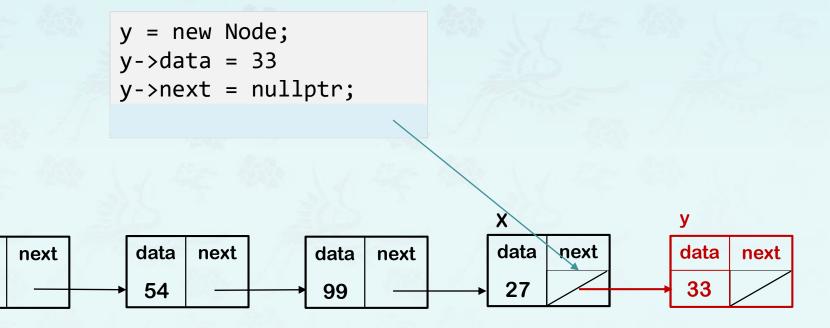

data

26

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Let us imagine that we have created a linked list, where **head** points to the head of the list and \mathbf{x} at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

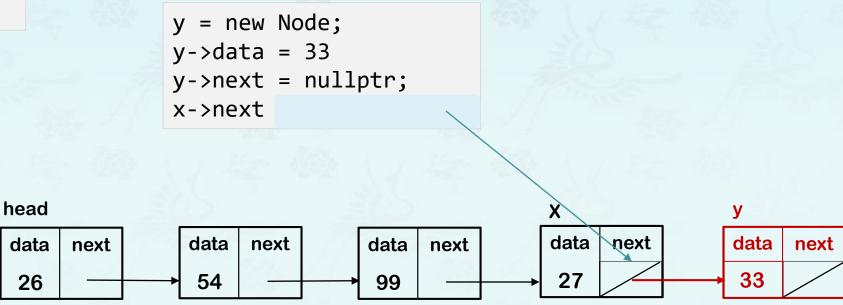

Add a node (n = 33) at the end of list.

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Let us imagine that we have created a linked list, where **head** points to the head of the list and \mathbf{x} at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

Add a node (n = 33) at the end of list.

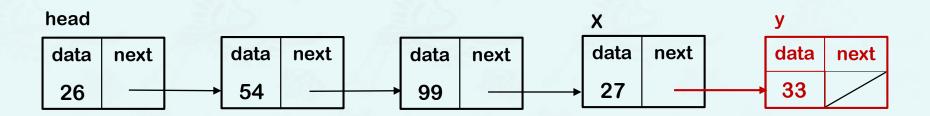

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Let us imagine that we have created a linked list, where **head** points to the head of the list and \mathbf{x} at the last item in the list (i.e. the one with the nullptr pointer) as shown below.

• Add a node (n = 33) at the end of list.

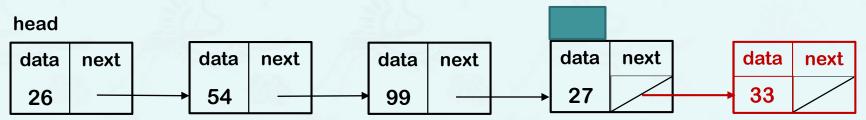

```
y = new Node;
y->data = 33
y->next = nullptr;
x->next = y;
```

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

 Add a node (n = 33) at the end of list, where only head of the list is given as shown below.

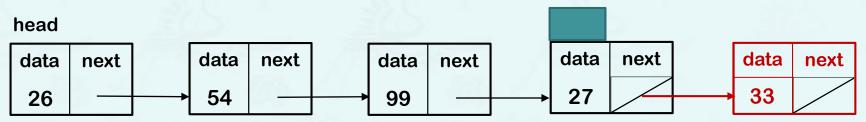

tail node is not given.

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Add a node (n = 33) at the end of list, where only head of the list is given as shown below.
- To get to the tail we have to scroll along the list until the end. We want
 a pointer that will stop while still pointing at the last node. Thus our
 termination condition is that the node's next field is nullptr. Once we
 have a pointer to the end of the list, we can make it point to the node
 we want to add:

tail node is not given.

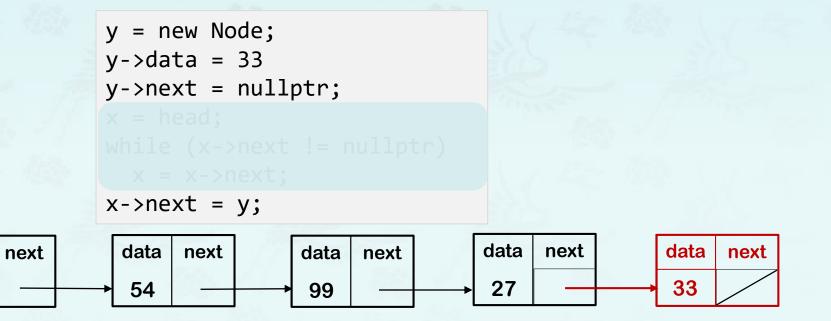

head

data

26

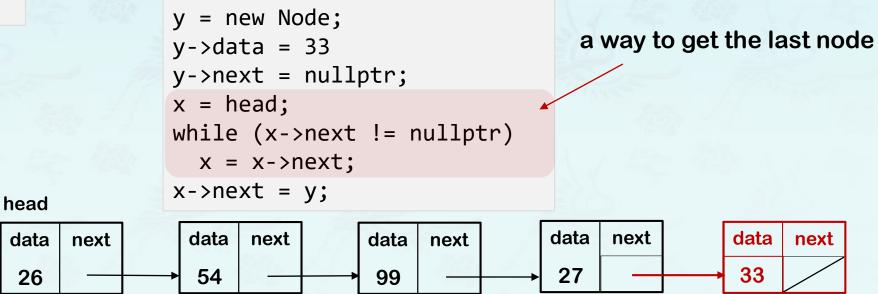

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Add a node (n = 33) at the end of list, where only head of the list is given as shown below.
- To get to the tail we have to scroll along the list until the end. We want
 a pointer that will stop while still pointing at the last node. Thus our
 termination condition is that the node's next field is nullptr. Once we
 have a pointer to the end of the list, we can make it point to the node
 we want to add:

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

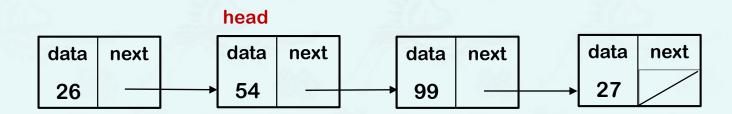

- Add a node (n = 33) at the end of list, where only head of the list is given as shown below.
- To get to the tail we have to scroll along the list until the end. We want
 a pointer that will stop while still pointing at the last node. Thus our
 termination condition is that the node's next field is nullptr. Once we
 have a pointer to the end of the list, we can make it point to the node
 we want to add:

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Remove the first node or move head to the next node.
 Then what is wrong with the following code?

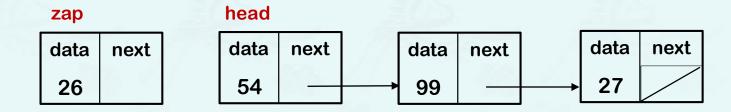

```
head = head->next;
```

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Remove the first node or move head to the next node.
 Then what is wrong with the following code?
- When removing a node, beware of memory leak; remember to give yourself a pointer to the node that is about to be removed before you lose your pointer to it:

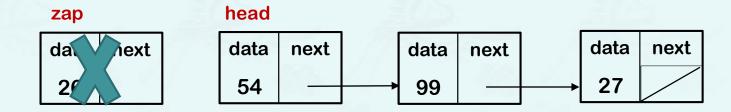

```
Node* zap = head;
head = head->next;
```

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Remove the first node or move head to the next node.
 Then what is wrong with the following code?
- When removing a node, beware of memory leak; remember to give yourself a pointer to the node that is about to be removed before you lose your pointer to it:

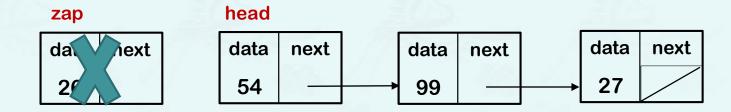

```
Node* zap = head;
head = head->next;
```

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

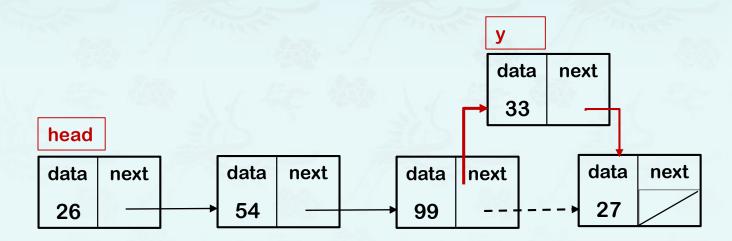

- Remove the first node or move head to the next node.
 Then what is wrong with the following code?
- When removing a node, beware of memory leak; remember to give yourself a pointer to the node that is about to be removed before you lose your pointer to it:

```
Node* zap = head;
head = head->next;
delete zap;
```

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Insert a node (n = 33) after the node (n = 99) as shown below.

head

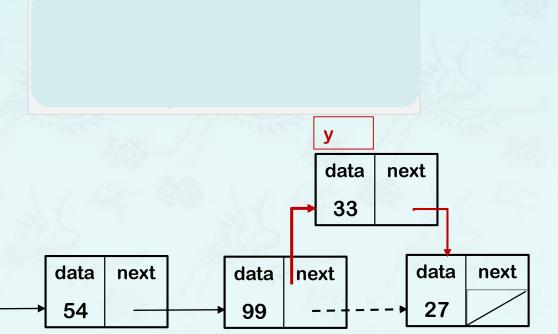

data

26

next

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Insert a node(n = 33) after the node (n = 99) as shown below.
- Starting from the head node, we have to stop at the node (n = 99) before the insertion point. Remember that a singly-linked list is a one way street!

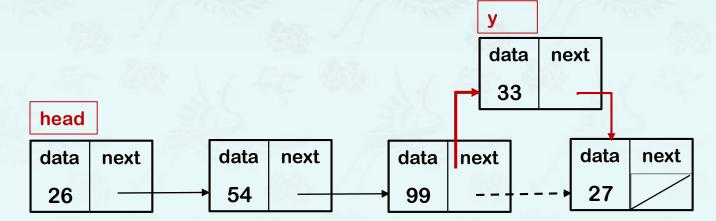

x = head;

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

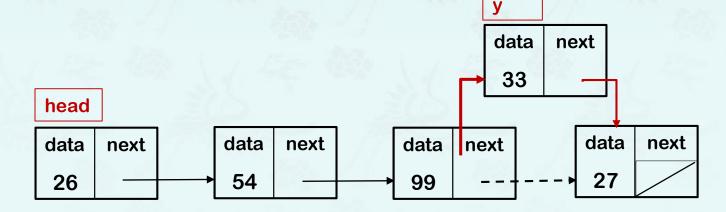

- Insert a node (n = 33) after the node (n = 99) as shown below.
- Starting from the head node, we have to stop at the node (n = 99) before the insertion point. Remember that a singly-linked list is a one way street!

```
x = head;
while (x->data != 99)
x = x->next; Where is x pointing after while()?
```

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

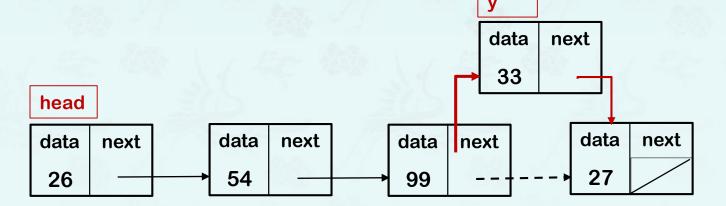

- Insert a node (n = 33) after the node (n = 99) as shown below.
- Starting from the head node, we have to stop at the node (n = 99) before the insertion point. Remember that a singly-linked list is a one way street!

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

- Insert a node (n = 33) after the node (n = 99) as shown below.
- Starting from the head node, we have to stop at the node (n = 99) before the insertion point. Remember that a singly-linked list is a one way street!

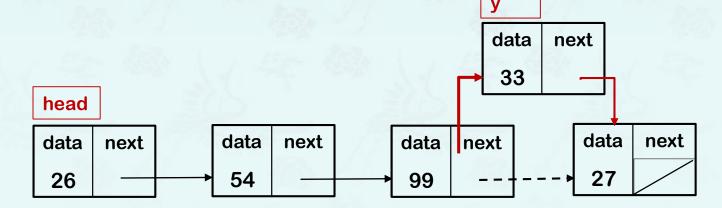

```
x = head;
while (x->data != 99)
  x = x->next;
y->next = x->next;
x->next =
```

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

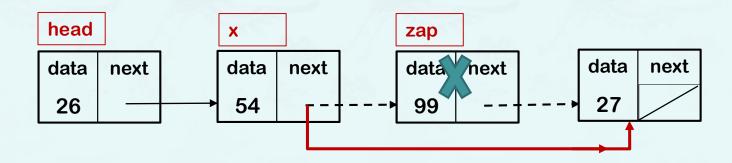

- Insert a node (n = 33) after the node (n = 99) as shown below.
- Starting from the head node, we have to stop at the node (n = 99) before the insertion point. Remember that a singly-linked list is a one way street!

```
x = head;
while (x->data != 99)
  x = x->next;
y->next = x->next;
x->next = y;
```

```
class Node {
public:
   int   data;
   Node* next;
};
...
Node* head, *x, *y;
```

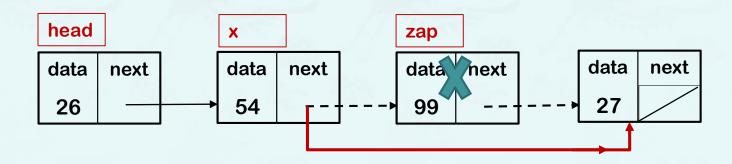

• Remove a node (n = 99) in the middle of list as shown below.

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

• Remove a node(n = 99) in the middle of list as shown below.

- use a handle pointer (zap here) to keep hold of the unwanted node
- find the node **before** the unwanted node and make links.
- delete the unwanted node

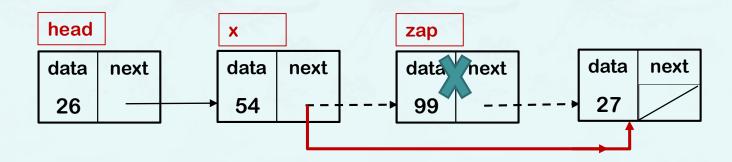

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

• Remove a node(n = 99) in the middle of list as shown below.

- use a handle pointer (zap here) to keep hold of the unwanted node
- find the node **before** the unwanted node and make links.
- delete the unwanted node

```
node* x = head, *zap = head->next;
while(zap->data!= 99) {
    x = zap;
    zap = zap->next;
}
To find both x and zap.

Assuming (1) there are at least two nodes,
(2) 99 is not the head node, and
(3) there is a 99 node.
```

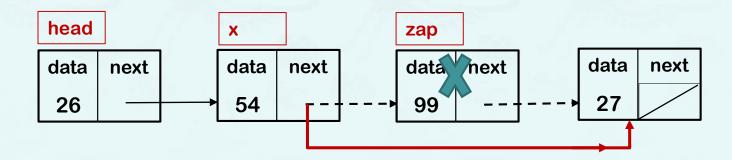

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

• Remove a node(n = 99) in the middle of list as shown below.

- use a handle pointer (zap here) to keep hold of the unwanted node
- find the node **before** the unwanted node and make links.
- delete the unwanted node

```
node* x = head, *zap = head->next;
while(zap->data!= 99) {
    x = zap;
    zap = zap->next;
}
x->next =
To find both x and zap.

Assuming (1) there are at least two nodes,
(2) 99 is not the head node, and
(3) there is a 99 node.
```

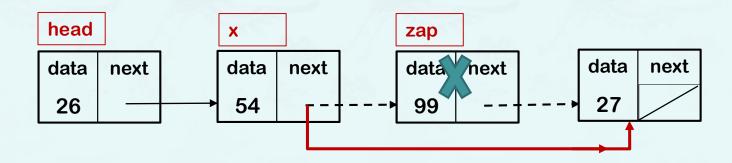

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

• Remove a node(n = 99) in the middle of list as shown below.

- use a handle pointer (zap here) to keep hold of the unwanted node
- find the node **before** the unwanted node and make links.
- delete the unwanted node

```
node* x = head, *zap = head->next;
while(zap->data!= 99) {
    x = zap;
    zap = zap->next;
}
x->next = zap->next;
To find both x and zap.

Assuming (1) there are at least two nodes,
(2) 99 is not the head node, and
(3) there is a 99 node.
```

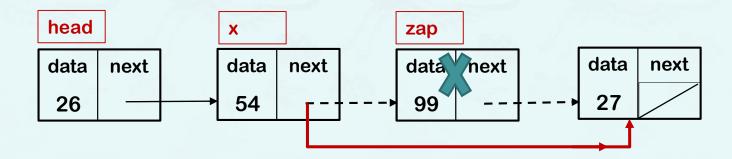

```
class Node {
public:
   int data;
   Node* next;
};
...
Node* head, *x, *y;
```

Remove a node(n = 99) in the middle of list as shown below.
